#### Abstract

We report the chemical synthesis of six oxidized derivatives of MK-0476 (Montelukast, L-706631), which have been key tools in the identification of its metabolites. We have prepared three diastereoisomeric pairs of potential oxidative metabolites of MK-0476, starting from the (S)-hydroxy ester 7 in 10 and five steps, and starting from MK-0476 itself in one step. The key benzylic hydroxyl of $\mathbf{1}$ and $\mathbf{2}$ was introduced by a bromination and saponification reaction sequence. In the case of the hydroxyl of $\mathbf{3}$ and $\mathbf{4}$, the key step was the addition of a hydroxymethyl carbanion equivalent on ketone 20. The two sulfoxide 5 and 6 were prepared by a direct oxidation of MK-0476 with m-chloroperbenzoic acid.

## Introduction

MK-0476 (M ontelukast, L-706631) is a potent, orally active cys-LT $T_{1}$ (leukotriene $\mathrm{D}_{4}$ ) receptor antagonist. ${ }^{1}$ As this compound progressed through clinical trials, ${ }^{2}$ it became important to characterize its metabolism. The preparation of oxidative metabolites of MK-0476 by microsomal oxidation in vitro has been described and several metabolites have been tentatively identified. ${ }^{3}$ We now report the chemical synthesis of six oxidized derivatives of MK-0476, which have been key tools in the identification of its metabolites.

## Results and Discussion

We elected to prepare authentic samples of the compounds which are proposed as metabolites based on the microsomal study on MK-0476 ${ }^{3}$ and on previously reported metabolism of similar molecules. ${ }^{4}$ To help clarify the regiochemistry of metabolic oxidation, the diastereomeric pairs 1 and 2, and $\mathbf{3}$ and 4, as well as the sulfoxides 5 and 6, were selected and prepared (Scheme 1). A straightforward approach to the synthesis of diastereoisomers $\mathbf{1}$ and $\mathbf{2}$ would be a direct benzylic oxidation at the C-21 position from the readily available MK-0476. Oxidants known to perform this type of transformation include ceric ammonium nitrate in acetic acid, ${ }^{5}$ selenium dioxide in acetic acid or in xylene, ${ }^{6}$ and DDQ. ${ }^{7}$ Unfortunately, all attempts to carry out the

[^0]oxidation using these reagents were unsuccessful due to the presence of the thioether moiety, which underwent rapid oxidation to sulfoxide or sulfone. Another decomposition pathway was also present for the reactions performed in acidic media, namely the dehydration of the tertiary alcohol of MK-0476 to give the styrene analog. A multistep synthesis was then devised starting from the available intermediate (S)-hydroxy ester 7, an intermediate in the synthesis of MK-0476 (Scheme 2). ${ }^{1}$

Protection of the C-19 hydroxyl as an acetate by treatment with $\mathrm{Ac}_{2} \mathrm{O}$ in the presence of $\mathrm{Et}_{3} \mathrm{~N}$ yielded $\mathbf{8}$ in quantitative yield. The desired oxidation state at C-21 for $\mathbf{1}$ and $\mathbf{2}$ was obtained by bromination of the ester $\mathbf{8}$ with NBS in the presence of a catalytic amount of benzoyl peroxide, providing a 1:1 diastereoisomeric mixture of benzylic bromides 9a,b in $69 \%$ yield. All attempts to improve this yield by varying the reaction conditions such as the amount of reactants (NBS, $\left.(\mathrm{BzO})_{2}\right)$ or running the reaction at higher concentration led to the formation of larger amounts of polybrominated material. The introduction of the hydroxyl functionality was performed on the mixture of bromo esters 9 via a nucleophilic displacement of the bromide by hydroxide, in what is presumably a multiple-step reaction amounting to a saponification and lactonization sequence. The process was carried out as a one-pot procedure, starting by saponification of the methyl ester and of the acetate with 4 equiv of LiOH in a mixture of water, THF , and MeOH . The newly formed carboxylate then displaced the benzylic bromide to generate a mixture of the hydroxylactones 10a,b, which could be transiently observed by TLC. These intermediates were further hydrol yzed to a nonmobile TLC spot, probably the mixture of hydroxycarboxylates. The reaction mixture was then treated with TFA to regenerate 10a,b by lactonization. Interestingly, the basic hydrolysis step led to the formation of side products, which arose from a Grob fragmentation and Cannizzaro dismutation. Under these basic conditions, the hydrolysis of the acetyl protecting group occurred readily, and the resulting alkoxide intermediate underwent fragmention to give 11 and $\mathbf{1 2}$ (Scheme 3). The aldehyde 11 reacted further with LiOH to afford Cannizzaro reaction-derived benzylic alcohol 13 and benzoic acid derivative 14. After careful optimization of the amount of LiOH , the reaction produced a limited amount of aldehyde $\mathbf{1 1}(<5 \%)$ and a trace

of Cannizaro products ( $\mathbf{1 3}$ and $\mathbf{1 4}$ ), while giving the desired material 10 in 64\% overall yield as a mixture of diastereoisomers.

We next proceeded to assign the relative configuration of the two hydroxylactones $\mathbf{1 0 a} \mathbf{a} \mathbf{b}$. We elected to prepare a cydic structure generated from a 1,3-diol derivative of 10. The initial attempts at the preparation of the 1,3diol intermediate involved a nucleophilic ring opening of lactones $\mathbf{1 0}$ with methylmagnesium chloride to give the mixture of triols $\mathbf{1 5}$ (Scheme 4). Unfortunately, all attempts to generate the corresponding cyclic acetonide or benzylidene failed, giving mostly cydic ethers. Alternatively, the preparation of a 1,3-diol methyl benzoate derivative (16) from acidic or basic methanolysis also failed, as only starting material was recovered. This observation demonstrated the need for a different nucleophile in the lactone ring opening, which would give a 1,3-diol derivative with less propensity to return to the
lactone. Thus, treatment of a mixture of hydroxylactones 10 with magnesium piperidide (Scheme 5) gave the desired diastereoisomeric 1,3-di hydroxyamide compounds 17, isolated in $90 \%$ yield. The diols 17 were treated with benzaldehyde dimethyl acetal and phosphorus oxychloride in $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ to provide the mixture of diastereoisomeric benzylidene amides 18, accompanied by only a trace amount of Iactonization. The diastereoisomers 18 were easily separated by flash chromatography. The relative stereochemistry of the benzylidenes was determined by analysis of coupling constants and NOE measurements. For benzylidene 18b, strong NOE's were observed between all three of the benzylidene methine protons, indicating that these were all axial and on the same side of the ring. The large three-bond coupling constants of 10.9 Hz for ${ }^{3}{ }^{3}$ 19,20ax and ${ }^{3}{ }^{3}$ 21,20ax also indicated a syn stereochemistry. In the case of 18a, a strong NOE was observed between the acetal methine and only one of the

Scheme 4

other two benzylidene methines. This same benzylidene methine had a large three-bond coupling constant of 11.0 Hz to the axial proton at $\mathrm{H}-20$, whereas the remaining benzylidene methine had a coupling constant of 5.3 Hz with the axial proton at $\mathrm{H}-20$. These results are consistent with an anti configuration for 18a. The anti-benzylidene 18a and syn-benzylidene 18b were respectively hydrolyzed to anti-hydroxylactone 10a and syn-hydroxylactone $\mathbf{1 0 b}$ using TFA in aqueous THF.

With the pure diastereoisomers $\mathbf{1 0}$ in hand, the synthesis of $\mathbf{1}$ and $\mathbf{2}$ could be continued. The secondary alcohols were mesylated, ${ }^{1}$ but these mesylates were insoluble and, therefore, unreactive under the conditions of the thiol displacement. However, the butanesulfonates 19 prepared from butanesulfonyl chloride were more soluble and reacted cleanly with the dianion of 1-(mer-captomethyl)-1-cyclopropaneacetic acid to give the respective compounds (Scheme 6).

In the final step of the sequence, organocerium addition on 20a,b using 5 equiv of methylmagnesium chloride and 1.5 equiv of $\mathrm{CeCl}_{3}{ }^{8}$ at $40{ }^{\circ} \mathrm{C}$ for 10 min generated the desired materials $\mathbf{1}$ and $\mathbf{2}$, respectively. Longer reaction times or excess reagent gave lower yields. I somers 1 and $\mathbf{2}$ were found to have fairly different retention times on HPLC and flash chromatography. Therefore, while benzylidenes 18 were key in the assignment of the configuration of hydroxylactones $\mathbf{1 0}$ and, therefore, of $\mathbf{1}$ and 2, scaling-up the synthesis of $\mathbf{1}$ and $\mathbf{2}$ only required a threestep sequence from the mixtures of isomers $\mathbf{1 0 a}, \mathbf{b}$ and separation of $\mathbf{1}$ and $\mathbf{2}$ in the last step for an overall yield of $16 \%$.

The synthesis of the other diastereomeric 1,2-diols 3 and 4 was also studied. The straightforward dihydroxyIation of the styryl analog of $\mathrm{MK}-0476$ with $\mathrm{OsO}_{4} / \mathrm{NMO}^{9}$ or AD-mix mixtures ${ }^{10}$ failed to give any desired material (Scheme 7). The thioether moiety once again underwent rapid oxidation to sulfoxide and sulfone. Given this intrinsic sensitivity of MK-476 toward oxidants, a multistep preparation of the diastereoisomeric metabolites 3 and 4 was devised (Scheme 8). The (S)-hydroxy ester 7 was converted to ketone 22 via the organomagnesium compound prepared in THF from lithium hexamethyldisilazide and methylmagnesium chloride. ${ }^{11}$ The addition of a hydroxymethyl carbanion equivalent generated from [(methoxymethoxy)methyl]tributylstannane ${ }^{12}$ and n-BuLi to the ketone $\mathbf{2 2}$ gave a 1:1 mixture of diastereoisomers 23a,b in 32\% yield, along with 44\% recovered starting material. The thiol acid side chain of $\mathbf{3}$ and 4 was introduced by selective mesylation of the secondary alcohol, giving mesylates 24a,b, followed by displacement with the dianion of 1-(mercaptomethyl)-1-cyclopropaneacetic acid to provide the acids 25 . Esterification using diazomethane and removal of the MOM protecting group using pyridinium p-toluenesulfonate in tert-butyl al cohol afforded a 1:1 diastereoisomeric mixture of 26a,b. These compounds were best separated on a Chiralpak AD HPLC column to afford $\mathbf{3}$ and 4 in a $8 \%$ overall yield from 7. The absolute stereochemistry of the newly created chiral center in $\mathbf{3}$ and $\mathbf{4}$ has not yet been assigned.

The two diastereomeric MK-0476 sulfoxides 5 and 6 were readily prepared by oxidation of theTFA salt of MK0476 with m-chloroperbenzoic acid at $-20^{\circ} \mathrm{C}$ (Scheme 9). The two isomers were separated by flash chromatography. The absolute configuration at the sulfur atom is unknown at this time.

## Conclusion

We have described the synthesis of the three diastereoisomeric pairs of potential oxidative metabolites of MK-0476, starting from the (S)-hydroxy ester 7 in 10 and five steps, and starting from MK-0476 itself in one step. The key benzylic hydroxyl of $\mathbf{1}$ and $\mathbf{2}$ was introduced by a bromination and saponification reaction sequence. In the case of the hydroxyl of $\mathbf{3}$ and $\mathbf{4}$, the key step was the addition of a hydroxymethyl carbanion equivalent on ketone 20. The two sulfoxides 5 and 6 were prepared by a direct oxidation of MK-0476 with m-chloroperbenzoic acid. Comparison of these compounds with metabolites observed in humans and animals will be reported in a future article.

## Experimental Section

General. Melting points (uncorrected) were determined in an open capillary tube. ${ }^{1} \mathrm{H}$ and ${ }^{13} \mathrm{C}$ NMR spectra were recorded in deuterated acetone unless otherwise noted. All reactions were performed in the dark to avoid olefin isomerization in flame-dried glassware under nitrogen.
